Project Demo Video URL: _____

3. Project Overview

3.1 Project Description

AR Sea Battle is a two-player Augmented Reality implementation of the classic Battleship board game developed in Unity using the Vuforia Engine. The application uses image tracking to place two virtual 5×5 game boards on top of printed image markers.

Players take turns placing ships on their own board, pass the phone to the other player, exchange physical markers, and then alternate attacking each other's fleet. The application combines AR visualization with a traditional board game while demonstrating image tracking, user interaction, game state management, and mobile deployment.

3.2 Target Platform

Specify clearly:

☐ Desktop
X **Mobile AR (Android / iOS)**
☐ Meta Quest
☐ HoloLens

The application was developed for Android devices using Vuforia image tracking. Two printed image targets are recognized by the camera and used as anchors for spawning the virtual game boards.

4. Technologies and Tools Used

Unity Version: 6000.3.9f1 (Unity 6)

AR Framework (Vuforia/AR Foundation/ARCore/ARKit/Meta XR/MRTK): Vuforia Engine 11.4.4

Programming Language: C#

3D Modeling Tools (if any): None

Version Control: GitLab

Other Tools (e.g., Visual Studio, Figma, Photoshop, Illustrator): Visual Studio Code, Git, Git Bash

5. System Architecture

The project consists of a single Unity scene containing the AR Camera, Player 1 Image Target, Player 2 Image Target, GameManager, UI Canvas, and AudioManager.

The application is divided into several script groups:

Game Logic: GameManager, OceanBoard,Player, Ship, Cell

UI: GameUI, PlacementUI

Audio: AudioManager

Vuforia Image Targets initialize the virtual boards when the markers are detected, while GameManager controls the overall game flow, including ship placement, player turns, shooting, and victory conditions.

6. Main Features

Image Tracking

Two Vuforia image targets are used to create independent AR game boards.

Object Placement

A virtual 5×5 board is generated dynamically when a marker is detected.

UI Interaction

Players use dropdown menus and buttons to place ships and perform attacks.

Audio Integration

Different sounds are played for: ship placement, hit, miss, ship sunk, victory

Particle Effects

Particle systems provide visual feedback for successful hits and misses.

Game Logic

The application supports: ship placement validation, turn management, hit detection, ship sinking, victory detection, restart functionality

8. My Role in the Project

I designed, implemented, tested, and deployed the complete application. My responsibilities included AR integration, gameplay programming, UI implementation, debugging, Android deployment, and version control.

9. My Contribution

- Implemented the complete Battleship game logic, including ship placement, turn management, hit detection, and victory conditions.
- Integrated Vuforia Engine and dynamic image-target-based board generation.
- Designed and implemented the user interface, pass-the-phone workflow, coordinate labels, audio, and particle effects.
- Tested and deployed the Android application while maintaining the GitLab repository.

10. Workload Distribution

Group Member	Role	Contribution (%)
Arsenije Djordjevic	Developer	100%

Total must equal 100%.

11. Challenges and Solutions

Challenge 1 – Reliable Image Tracking

One image target had noticeably weaker tracking than the other. It was replaced with a new target containing more distinctive visual features, resulting in faster and more stable recognition.

Challenge 2 – Pass-the-Phone Gameplay

Since the game is played on a single device, clear transitions between players were required. A countdown and pass-the-phone panel were added to guide players through each phase.

Challenge 3 – User Interface

Combining AR visualization with traditional UI controls required several iterations. The interface was refined to improve readability, feedback, and ease of use on a mobile device.

Challenge 4 – Visual Clarity

The detailed image markers made the virtual board difficult to distinguish. An ocean base and slightly raised cells were added to improve contrast and create a more three-dimensional appearance.

Challenge 5 – Version Control

The Vuforia Unity package exceeded GitLab's file size limit. The repository was reorganized so large generated files were excluded while preserving the project's functionality.

12. Conclusion

This project provided practical experience with Augmented Reality application development using Unity and Vuforia. Throughout development I improved my understanding of image tracking, game state management, user interface design, Android deployment, and software version control.

Future improvements could include 3D ship models, gesture-based interaction instead of UI controls, online multiplayer support, and enhanced visual effects.

The final application was successfully deployed and tested on an Android device, demonstrating stable AR image tracking and complete gameplay functionality.
